In the nearby kindergarten they recently made up an attractive game of strength and agility that kids love.

The surface for the game is a large flat area divided into N imes N squares.

The children lay large spongy cubes onto the surface. The sides of the cubes are the same length as the sides of the squares. When a cube is put on the surface, its sides are aligned with some square. A cube may be put on another cube too.

Kids enjoy building forts and hiding them, but they always leave behind a huge mess. Because of this, prior to closing the kindergarten, the teachers rearrange all the cubes so that they occupy a rectangle on the surface, with exactly one cube on every square in the rectangle.

In one moving, a cube is taken off the top of a square to the top of any other square.

Write a program that, given the state of the surface, calculates the smallest number of moves needed to arrange all cubes into a rectangle.

Input Specification

The first line contains the integers N and M ($1 \le N \le 100, 1 \le M \le N^2$), the dimensions of the surface and the number of cubes currently on the surface.

Each of the following M lines contains two integers R and C $(1 \le R, C \le N)$, the coordinates of the square that contains the cube.

Output Specification

Output the smallest number of moves. A solution will always exist.

In the first example, it suffices to move one of the cubes from (1,1) to (1,2) or (2,1). In the third example, a cube is moved from (2,3) to (3,3), from (4,2) to (2,5) and from (4,4) to (3,5).
