**quantum** is not feeling well today, and so has decided to create a painful challenge for you.

You are given the following function `x`:

```
def outer():
    secret = <some special value you do not know>
    def inner():
        <does some magic with secret>
    return inner

x = outer()
del outer
```

You are to somehow obtain `secret` from `x`. Your code will be run after the above block of code.

To make your life harder, **quantum** decided that you should not be able to use `import`, or any other builtin for that matter. Obviously, you will be allowed to access `print`.

## Input Specification

---

There will not be input.

## Output Specification

---

The `str` representation of the `secret` variable.
